## **Google PlayStore Data**

#### **Complete Exploratory Data Analysis**

- AuthorShariq Nauman
- E-mail shariqnaumann@gmail.com

#### **About Dataset**

Source

This dataset was taken from Kaggle using the following link: https://www.kaggle.com/datasets/lava18/google-play-store-apps? resource=download

Context

While many public datasets (on Kaggle and the like) provide Apple App Store data, there are not many counterpart datasets available for Google Play Store apps anywhere on the web. On digging deeper, I found out that iTunes App Store page deploys a nicely indexed appendix-like structure to allow for simple and easy web scraping. On the other hand, Google Play Store uses sophisticated modern-day techniques (like dynamic page load) using JQuery making scraping more challenging.

Content

Each app (row) has values for catergory, rating, size, and more.

Acknowledgements

This information is scraped from the Google Play Store. This app information would not be available without it.

Inspiration

The Play Store apps data has enormous potential to drive app-making businesses to success. Actionable insights can be drawn for developers to work on and capture the Android market!

## **Importing Libraries**

```
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt
```

## **Data Exploration & Cleaning**

- C Load the csv file with the pandas library.
- Creating the dataframe and understanding the data present in the dataset using pandas.
- G Dealing with the missing data, outliers and the incorrect records.

```
In [ ]: df = pd.read_csv('./data/googleplaystore.csv')
```

Viewing the first five Rows of the data.

In [ ]: df.head(5)

Out[]:

	Арр	Category	Rating	Reviews	Size	Installs	Туре	Price	Cont Rat
0	Photo Editor & Candy Camera & Grid & ScrapBook	ART_AND_DESIGN	4.1	159	19M	10,000+	Free	0	Every

4									•

**Note**: Sometimes, the notebook does not present the complete output, therefore we can increase the limit of columns view and row view by using these commands:

```
In []: # Enabling the maximum rows & columns display option
pd.set_option('display.max_columns', None) # This is to display all the columns
pd.set_option('display.max_rows', None) # This is to display all the rows in the

# Disabling any unnecassary warnings for better representation
import warnings
warnings.filterwarnings('ignore')
```

 Lets see the exact column names which can be easily copied later on from Google Playstore Dataset.

```
In [ ]:
    columns = ''
    for i in range(len(df.columns)):
        columns += df.columns[i] + ', '
    print(f"The names of the columns are as follows: {columns[:len(columns)-2]}.")
```

The names of the columns are as follows: App, Category, Rating, Reviews, Size, In stalls, Type, Price, Content Rating, Genres, Last Updated, Current Ver, Android V er.

• Lets have a look on the shape of the dataset.

```
In [ ]: print(f"This dataset contains {df.shape[0]} rows & {df.shape[1]} columns.")
```

This dataset contains 10841 rows & 13 columns.

 Not enough, lets have a look on the columns and their data types using detailed info function.

```
In [ ]: df.info()
```

<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10841 entries, 0 to 10840
Data columns (total 13 columns):

#	Column	Non-Null Count	Dtype				
0	Арр	10841 non-null	object				
1	Category	10840 non-null	object				
2	Rating	9367 non-null	float64				
3	Reviews	10841 non-null	int64				
4	Size	10841 non-null	object				
5	Installs	10841 non-null	object				
6	Type	10840 non-null	object				
7	Price	10841 non-null	object

	4 4 . 14	<b>D</b>					

memory usage: 1.1+ MB

#### **Observations**

- 1. There are 10841 rows and 13 columns in the dataset.
- 2. The columns are of different data types.
- 3. The columns in the datasets are:
  - 'App', 'Category', 'Rating', 'Reviews', 'Size', 'Installs',
     'Type', 'Price', 'Content Rating', 'Genres', 'Last Updated',
     'Current Ver', 'Android Ver'
- 4. There are some missing values in the dataset which we will read in detail and deal later on in the notebook.
- 5. There are some columns which are of object data type but they should be of numeric data type, we will convert them later on in the notebook.
  - 'Size', 'Installs', 'Price'

#### In [ ]: df.describe()

# Out[]: Rating Reviews count 9367.000000 1.084100e+04

count	9367.000000	1.084100e+04
mean	4.191513	4.441119e+05
std	0.515735	2.927629e+06
min	1.000000	0.000000e+00
25%	4.000000	3.800000e+01
50%	4.300000	2.094000e+03
75%	4.500000	5.476800e+04
max	5.000000	7.815831e+07

## **Observations**

- We have only 2 columns as numeric data type, rest all are object data type
   (according to python), but we can see that 'Size', 'Installs', 'Price' are
   also numeric, we must convert them to numeric data type in data wrangling process.
- Let's clean the Size column first

```
In [ ]: # Counting the number of missing values in the column
df['Size'].isnull().sum()
```

Out[]: 0

• There are no missing values, so we are good to go.

```
In [ ]: # Check unique values
df['Size'].unique()
```

```

                 '743k', '116k', '153k', '209k', '353k', '499k', '173k', '597k',
                 '809k', '122k', '411k', '400k', '801k', '787k', '237k', '50k',
                 '643k', '986k', '97k', '516k', '837k', '780k', '961k', '269k', '20k', '498k', '600k', '749k', '642k', '881k', '72k', '656k',
                 '601k', '221k', '228k', '108k', '940k', '176k', '33k', '663k',
                 '34k', '942k', '259k', '164k', '458k', '245k', '629k', '28k',
                 '288k', '775k', '785k', '636k', '916k', '994k', '309k', '485k',
                 '914k', '903k', '608k', '500k', '54k', '562k', '847k', '957k',
                 '688k', '811k', '270k', '48k', '329k', '523k', '921k', '874k'
                 '981k', '784k', '280k', '24k', '518k', '754k', '892k', '154k',
                 '860k', '364k', '387k', '626k', '161k', '879k', '39k', '970k',
                 '170k', '141k', '160k', '144k', '143k', '190k', '376k', '193k',
                 '246k', '73k', '658k', '992k', '253k', '420k', '404k', '470k',
                 '226k', '240k', '89k', '234k', '257k', '861k', '467k', '157k',
                 '44k', '676k', '67k', '552k', '885k', '1020k', '582k', '619k'],
               dtype=object)
```

There are several uniques values in the Size column, we have to first convert each unit into one common unit (megabytes) for all values, and then remove the M and k from the values and convert them into numeric data type.

```
In [ ]: # Counting the number of values that contain 'k' in them
    df['Size'].loc[df['Size'].str.contains('k')].value_counts().sum()

Out[ ]: 316

In [ ]: # Counting the number of values that contain 'M' in them
    df['Size'].loc[df['Size'].str.contains('M')].value_counts().sum()

Out[ ]: 8830

In [ ]: # Counting the number of values that contain 'Varies with device' in them
    df['Size'].loc[df['Size'].str.contains('Varies with device')].value_counts().sum

Out[ ]: 1695

In [ ]: # Taking sum of all the values in size column which has 'M', 'K' and 'varies wit
    316+8830+1695 == len(df)
Out[ ]: True
```

- We have 8830 values that have M unit.
- We have 316 values that have k unit.
- We have 1695 values of Varies with device.

Let's convert the k units into megabytes and then remove the M and k from the values and convert them into numeric data type.

```
In [ ]: # Convert the size column to numeric by dividing the values with 1024 if it has
        def convert_to_mb(size):
            if 'k' in size:
                return float(size.replace('k', '')) / 1024
            elif 'M' in size:
                return float(size.replace('M', ''))
            else:
                return np.nan # Return NaN for unknown values
        # Applying the convert function to the Size column
        df['Size'] = df['Size'].apply(convert_to_mb)
In [ ]: # Converting the object data type into numeric (float) data type
        df['Size'] = pd.to numeric(df['Size'], errors='coerce')
        df['Size'].dtype
Out[]: dtype('float64')
In [ ]: # Renaming the Size column
        df.rename(columns={'Size': 'Size (MB)'}, inplace=True)
```

- Now we have converted every value into megabytes and removed the M and K from the values and converted them into numeric data type.
- 'Varies with device' was a string value, therefore we intentionally converted them into null values, which we can fill later on according to our needs.
- Lets have a look on the Installs column.

```
In [ ]: # Check the unique values in size column
        df['Installs'].unique()
Out[]: array(['10,000+', '500,000+', '5,000,000+', '50,000,000+', '100,000+',
               '50,000+', '1,000,000+', '10,000,000+', '5,000+', '100,000,000+',
               '1,000,000,000+', '1,000+', '500,000,000+', '50+', '100+', '500+',
               '10+', '1+', '5+', '0+', '0'], dtype=object)
In [ ]: # Lets have a values counts
        df['Installs'].value_counts()

        500,000,000+
                           67
        1,000,000,000+
                           58
                           14
        0
                            1
        Name: count, dtype: int64
In [ ]: # Counting the number of missing values in the column
        df['Installs'].isnull().sum()
Out[ ]: 0
In [ ]: # Find how many values has '+' in it
        df['Installs'].loc[df['Installs'].str.contains('\+')].value_counts().sum()
Out[ ]: 10840
```

The only problem I see here is the + and , signs.

- The total values in the Installs column are 10841 and there are no null values in the column.
- However, one value 0 has no plus sign.
- Let's remove the plus sign + and , from the values and convert them into numeric data type

```
In [ ]: # Remove the plus sign from install column and convert it to numeric
    df['Installs'] = df['Installs'].str.replace('+', '')
    # Also remove the commas from the install column
    df['Installs'] = df['Installs'].str.replace(',', '')
    # convert the install column to numeric (integers because this is the number of
    df['Installs'] = df['Installs'].astype('int64')
```

• Lets verify if the datatype has been changed and the + and , sign have been removed.

In [ ]: df.head() # Check the head of the dataframe

Out[]: dtype('int64')

```

Name: count, dtype: int64

We need to confirm if the values in the Price column are only with \$ sign or not.

```
In [ ]: # Counting the number of values in the 'Price' column that have $ in it
        df['Price'].str.startswith('$').sum()
Out[]: 800
In [ ]: # Counting the number of values in the 'Price' column that do not have $ in it
        df['Price'].str.startswith('0').sum()
Out[ ]: 10041
```

- Now we can confirm that the only currency used is \$ in the Price column, as 800+10041=10841 values, which is equal to the total number of rows in the dataframe.
- The only problem is \$ sign let's remove it and convert the column into numeric data type.

```
In [ ]: # Removing the $ sign from the 'Price' column and converting it to numeric (floa
        df['Price'] = df['Price'].str.replace('$', '')
```

#### **Descriptive Statistics**

In	Γ	1:	<pre>df.describe()</pre>
	L	١.	ar acscribe()

Out[ ]:		Rating	Reviews	Size (MB)	Installs	Price
	count	9367.000000	1.084100e+04	9146.000000	1.084100e+04	10841.000000
	mean	4.191513	4.441119e+05	21.514141	1.546291e+07	1.027273

	max	5.000000	7.815831e+07	100.000000	1.000000e+09	400.000000

#### **Observations**

- Now, we have only 5 columns as numeric data type.
- We can observe their descriptive statistics. and make tons of observations as per our hypotheses.
- We can see that the Rating column has a minimum value of 1 and a maximum value of 5, which is the range of rating, and the mean is 4.19 which is a good rating. On an average people give this rating.
- We can see that the Reviews column has a minimum value of 0 and a maximum value of 78,158,306 (78+ Million), which is the range of reviews, and the mean is 444,111.93 which is a good number of reviews. On an average people give this number of reviews to the apps. But it does not make sense to us, as we have different categories of apps.
- Similarly, we can observe the other columns as well.

Therefore, the most important thing is to classify as app based on the correlation matrix and then observe the descriptive statistics of the app category and number of installs, reviews, ratings, etc.

But even before that we have to think about the missing values in the dataset.

## **Dealing with missing values**

Dealing with the missing values is one of the most important part of the data wrangling process, we must deal with the missing values in order to get the correct insights from the data.

• Lets have a look on the missing values in the dataset.

```
In [ ]: # Counting the number of missing values in each column of the dataframe and disp
        df.isnull().sum().sort_values(ascending=False)

                            0.000000
        dtype: float64
```

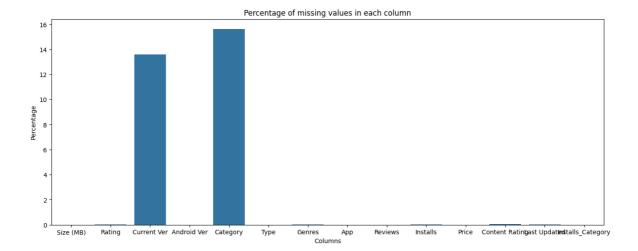

• Lets plot the missing values on a heatmap.

```
In []: # setting the figure size
    plt.figure(figsize=(16, 6))
    # plotting the missing values on a heatmap using seaborn
    sns.heatmap(df.isnull(), cbar=False)
    # displaying the plot
    plt.show()
```

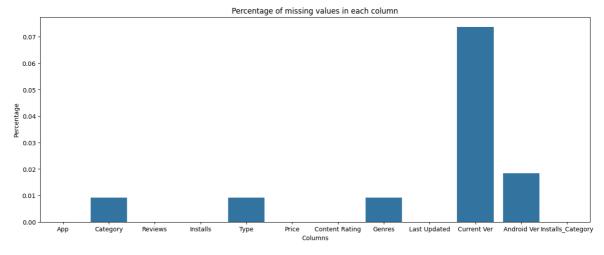

Now, lets plot the missing values by their percentage on a bar plot.

```
In []: # setting figure size
    plt.figure(figsize=(16, 6))
    # plotting the missing values by their percentage on a bar plot
    sns.barplot(x=(df.isnull().sum() / len(df) * 100).sort_values(ascending=False).i
    plt.xlabel('Columns')
    plt.ylabel('Percentage')
    plt.title('Percentage of missing values in each column')
    # displaying the plot
    plt.show()
```

• We have missing percentage columns that have less than one percent of missing values, we will plot them as follows:

```
In []: # setting the figure size
    plt.figure(figsize=(16, 6))
    # plotting the missing values of the columns that have percentage less than 1 on
    sns.barplot(x=(df.isnull().sum() / len(df) * 100)[(df.isnull().sum() / len(df) *
    plt.xlabel('Columns')
    plt.ylabel('Percentage')
    plt.title('Percentage of missing values in each column')
    # displaying the plot
    plt.show()
```

#### **Observations**

- We have 1695 missing values in the 'Size\_in\_bytes' and 'Size\_in\_Mb' columns, which is 15.6% of the total values in the column.
- We have 1474 missing values in the 'Rating' column, which is 13.6% of the total values in the column.
- We have 8 missing value in the 'Current Ver' column, which is 0.07% of the total values in the column.
- We have 2 missing values in the 'Android Ver' column, which is 0.01% of the total values in the column.

- We have only 1 missing value in Category, Type and Genres columns, which is 0.009% of the total values in the column.
- We can not impute the Rating column as it is directly linked with the Installs column. To test this Hypothesis, we need to plot the Rating column with the Installs and Size columns and statistically test it using pearson correlation test.
- Lets run the correlations.

In [ ]: # Displays the numeric columns with their summary statistics
 df.describe()

Out[ ]:		Rating	Reviews	Size (MB)	Installs	Price
	count	9367.000000	1.084100e+04	9146.000000	1.084100e+04	10841.000000
	mean	4.191513	4.441119e+05	21.514141	1.546291e+07	1.027273

	Price	-0.021851	-0.009666	-0.023000	-0.011688	1.000000

```
In []: # We can calculate the pearson correlation coefficient using scipy
    from scipy import stats

# Remove rows containing NaN or infinite values (Important to calculate Pearson'
    df_clean = df.dropna()

# calculate Pearson's R between Rating and Installs
    pearson_r, _ = stats.pearsonr(df_clean['Reviews'], df_clean['Installs'])
    print(f"Pearson's R between Reviews and Installs: {pearson_r:.4f}")
```

Pearson's R between Reviews and Installs: 0.6262

#### **Observations**

- Lighter color shows the high correlation and darker color shows the low correlation.
- We can see that the Reviews column has a high correlation with the Installs column, which is 0.64 according to corr(), which is quite good.

- This shows that the more the reviews the more the installs are for one app. If in any case we need to impute reviews we have to think of number of install.
- If we have an app with 2 installs and we imputer the reviews with 1000 or via average reviews then it will be wrong.
- Installs is slightly correlated with Size (MB), which is 0.16, this also shows us the importance of Size and Installs. But we can not depend on it as the Pearson correlation is very low.
- Before going ahead, let's remove the rows with missing values in the Current
   Ver , Android Ver , Category , Type and Genres columns, as they are very less in number and will not affect our analysis.

```
In []: # Length beofre removing the null values
    print(f"Length of the dataframe before removing the null values: {len(df)}")
    Length of the dataframe before removing the null values: 10841
In []: # Removing the rows having null values in 'Cureent Ver', 'Android Ver', 'Genres'
    df.dropna(subset=['Current Ver', 'Android Ver', 'Genres', 'Category', 'Type'], i
In []: # Length after removing the null values
    print(f"Length of the dataframe after removing the null values: {len(df)}")
    Length of the dataframe after removing the null values: 10829
```

• We have removed 12 rows having null values in the Current Ver , Android

Ver , Category , Type and Genres columns.

```
In [ ]: # Lets check the null values again
       df.isnull().sum().sort_values(ascending=False)

#### **Observations**

• Only Rating and Size (MB) columns are left with missing values.

- We know that we have to be carefull while deadling with Rating column, as it is directly linked with the Installs column.
- In Size columns, we already know about Varies with device values, which we have converted into null values, we do not need to impute at the moment, as every app has different size and nobody can predict that as accurately as possible.

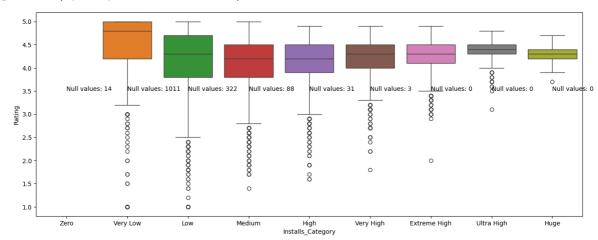

```

                            0
         Huge
         Name: count, dtype: int64
```

Let's plot this and have a look.

```
In []: # Plot the boxplot of Rating in each Installs_category
    plt.figure(figsize=(16, 6)) # make figure size
    sns.boxplot(x='Installs_Category', y='Rating', hue='Installs_Category', data=df)

# Add the text of number of null values in each category
    plt.text(0, 3.5, 'Null values: 14')
    plt.text(1, 3.5, 'Null values: 1011')
    plt.text(2, 3.5, 'Null values: 322')
    plt.text(3, 3.5, 'Null values: 88')
    plt.text(4, 3.5, 'Null values: 31')
    plt.text(5, 3.5, 'Null values: 3')
    plt.text(6, 3.5, 'Null values: 0')
    plt.text(7, 3.5, 'Null values: 0')
    plt.text(8, 3.5, 'Null values: 0')
```

#### Out[]: Text(8, 3.5, 'Null values: 0')

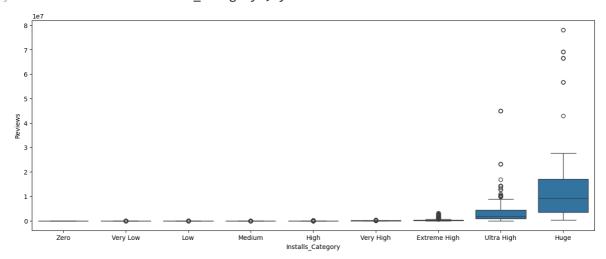

Let's check if there is any similar link with Reviews as well

```
In [ ]: # In which Install_category the Reviews has NaN values
        df['Installs_Category'].loc[df['Reviews'].isnull()].value_counts()
Out[]: Installs Category
         Zero
                         a
         Very Low
                         0
                         0
         Low
         Medium
                         0
                         a
         High
         Very High
         Extreme High
                         0
         Ultra High
                         0
         Huge
                         0
         Name: count, dtype: int64
```

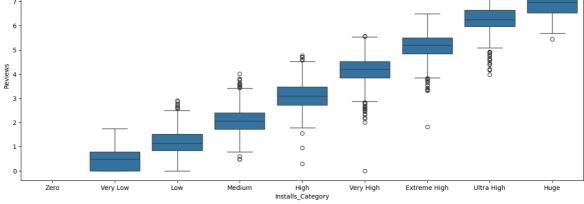

• There are no Null values in Reviews.

```
In [ ]: # Let's plot the same plots for Reviews column as well
    plt.figure(figsize=(16, 6)) # make figure size
    sns.boxplot(x='Installs_Category', y= 'Reviews', data=df) # plot the boxplot
```

Out[ ]: <Axes: xlabel='Installs\_Category', ylabel='Reviews'>

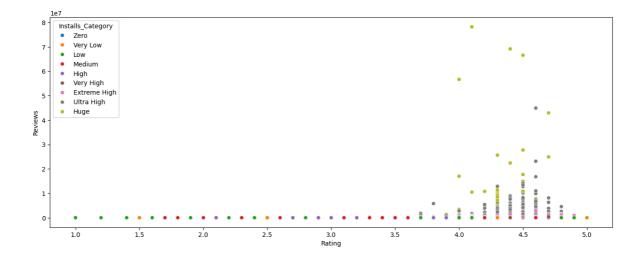

• The data looks really imbalance, let's normalize the data using log transformation.

• We also draw the scatter plot of the Rating and Review columns with the Installs column.

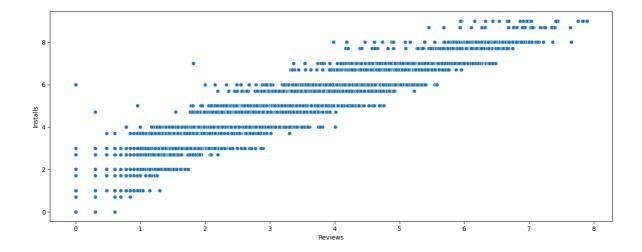

```
In [ ]: # Draw a scatter plot between Rating, Reviews and Installs
    plt.figure(figsize=(16, 6)) # make figure size
    sns.scatterplot(x='Rating', y='Reviews', hue='Installs_Category', data=df) # plo
Out[ ]: <Axes: xlabel='Rating', ylabel='Reviews'>
```

- It doesn't show any trend, because, you should know that Rating is a categorical variable (Ordinal) and Reviews is a continuous variable, therefore, we can not plot them together.
- Let's try with Reviews and Installs

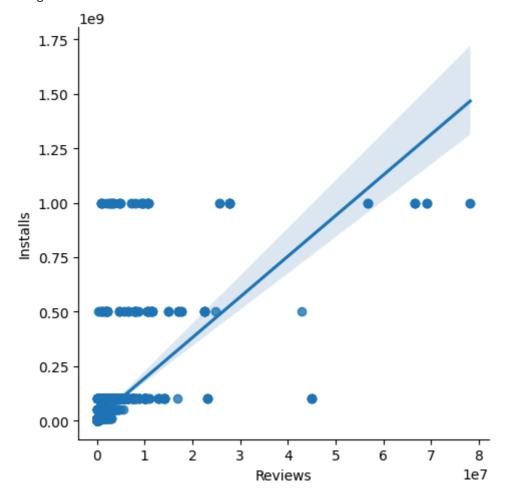

• We did not see any trend and the issue is we need to normalize the data before plotting it, let's try with log transformation.

```
In [ ]: # Plot reviews and installs in a scatter plot
    plt.figure(figsize=(16, 6)) # make figure size
    sns.scatterplot(x=np.log10(df['Reviews']), y=np.log10(df['Installs']), data=df)
Out[ ]: <Axes: xlabel='Reviews', ylabel='Installs'>
```

• Now we see a slight trend but still the issue is installs were given in a factorial manner such as 10+, 20+, 1000+ etc, and these are not continuous, instead they are discrete, therefore, we can only see a slight trend here. Let's plot a line plot to see the trend.

```
In [ ]: # Plot reviews and installs in a scatter plot with trend line
    plt.figure(figsize=(16, 6)) # make figure size
    sns.lmplot(x='Reviews', y='Installs', data=df) # plot the scatter plot with tren
```

• Here, we can see a nice trend, which shows that number of Reviews increases with the number of Installs, which is quite obvious.

#### **Observation**

- We can see that most of the null values from Rating column are No Moderate Installation apps, which make sense that if the app has less installations, it has less Rating and Reviews.
- But wait, we have to check for the duplicates as well, as they can affect our analysis.

### **Duplicates**

- Removing duplicates is one of the most important part of the data wrangling
  process, we must remove the duplicates in order to get the correct insights from the
  data.
- If you do not remove duplicates from a dataset, it can lead to incorrect insights and analysis.
- Duplicates can skew statistical measures such as mean, median, and standard deviation, and can also lead to over-representation of certain data points.
- It is important to remove duplicates to ensure the accuracy and reliability of your data analysis.

```
In [ ]: # Find duplicate if any
df.duplicated().sum()
```

Out[]: 483

This shows us total duplicates, but we can also check based on the app name, as we know that every app has a unique name.

```
In [ ]: # Find duplicate if any in the 'App' column
df['App'].duplicated().sum()
```

Out[ ]: 1181

- Oops! we have 1181 dupicate app names.
- Can we find a column which can help us to remove the duplicates?

Let's check for number of duplicates in each column using a for loop and print the output.

```
In [ ]: # Let's check for number of duplicates
for col in df.columns:
    print(f"Number of duplicates in {col} column are: {df[col].duplicated().sum(
```

```
Number of duplicates in App column are: 1181

Number of duplicates in Category column are: 10796

Number of duplicates in Rating column are: 10789

Number of duplicates in Reviews column are: 4830

Number of duplicates in Size (MB) column are: 10373

Number of duplicates in Installs column are: 10809

Number of duplicates in Type column are: 10827

Number of duplicates in Price column are: 10737

Number of duplicates in Content Rating column are: 10823

Number of duplicates in Genres column are: 10710

Number of duplicates in Last Updated column are: 9453

Number of duplicates in Current Ver column are: 7998

Number of duplicates in Android Ver column are: 10796

Number of duplicates in Installs_Category column are: 10820
```

• Find and watch all duplicates if they are real!

```
In [ ]: # Find exact duplicates and print them
df[df['App'].duplicated(keep=False)].sort_values(by='App').head(19)
```

• Remove Duplicates.

```
In []: # Remove the duplicates from app column
    df.drop_duplicates(subset='App', keep='first', inplace=True)

In []: # Print the number of rows and columns after removing duplicates
    print(f"Number of rows after removing duplicates: {df.shape[0]}")
```

Number of rows after removing duplicates: 9648

Now we have removed 1181 duplicates from the dataset, and have 9648 rows left.

## **Insights from Data**
